NT-2: Entire-Function Structure of the SCT Spectral Form Factors

From Taylor Analyticity to Ghost-Freedom Bounds

David Alfyorov

Abstract

We establish the entire-function structure of the nonlocal form factors $F_1(z)$ and $F_2(z,\xi)$ that govern the one-loop curvature-squared sector of the Spectral Chamseddine–Connes–van Suijlekom (SCT) action. Starting from the master function $\phi(z) = e^{-z/4}\sqrt{\pi/z}\,\mathrm{erfi}(\sqrt{z}/2)$, we prove that ϕ is entire via its convergent Taylor representation. We then show that all per-spin Codello–Zanusso form factors $h_C^{(s)}$ and $h_R^{(s)}$ $(s = 0, 1/2, 1)$ are entire despite their apparent poles at $z = 0$. The cancellation is established analytically by showing that $z^2 h(z)$ has a double zero at the origin and confirmed numerically to 10^{-15} precision.

We further derive that F_1 and F_2 have entire-function order $\rho = 1$ and type $\sigma = 1/4$, and we characterize their zero structure via Hadamard factorization. The auxiliary NT-2 proxy $\Pi_{\text{proxy}}(z) = 1 + c_2\, z\, \hat{F}_1(z)$ is analysed only as a proxy object. A later direct NT-4a re-audit shows that the normalized spin-2 denominator itself develops a positive-real-axis zero, so NT-2 by itself does *not* settle ghost-freedom of the physical propagator. Five mandatory cross-checks (local limit, beta coefficients, UV decay, dimensional analysis, and literature comparison) all pass. All key identities are formally verified in Lean 4 (Mathlib4 + Aristotle).

1 Introduction

The spectral action principle of Chamseddine and Connes [1] produces an effective gravitational action from the spectrum of the Dirac operator on a noncommutative geometry. At one-loop order, the curvature-squared sector of the SCT action takes the nonlocal form

$$\Gamma^{(1)} = \frac{1}{16\pi^2} \int \mathrm{d}^4x \sqrt{g} \left[F_1\left(\frac{\Box}{\Lambda^2}\right) C_{\mu\nu\rho\sigma} C^{\mu\nu\rho\sigma} + F_2\left(\frac{\Box}{\Lambda^2}\right) R^2 \right], \tag{1}$$

where Λ is the noncommutativity scale, $\Box = g^{\mu\nu}\nabla_\mu\nabla_\nu$ is the covariant d'Alembertian, and F_1, F_2 are nonlocal form factors that encode the UV behaviour of each spin species propagating in the loop.

The analytic structure of F_1 and F_2 is of direct physical importance:

- *Ghost-freedom.* Poles of F_i on the positive real axis of $z = -k^2/\Lambda^2$ would produce ghost modes in the linearized propagator. Their absence is a necessary condition for unitarity.
- *UV finiteness.* The growth rate of F_i at large $|z|$ controls the UV convergence of higher-loop diagrams and determines whether the nonlocal action is super-renormalizable.
- *Causal structure.* Entire-function form factors lead to nonlocal operators $\exp(-\Box/\Lambda^2)$ whose Green's functions preserve macroscopic causality [5, 6].

This document establishes three main results:

1. $F_1(z)$ and $F_2(z,\xi)$ are entire functions of $z \in \mathbb{C}$ (theorem 5.1).
2. Their entire-function order is $\rho = 1$ and type is $\sigma = 1/4$ (theorem 6.3).
3. The proxy zero scan used in NT-2 is informative about the complex analytic structure of the form factors, but does not by itself settle the physical propagator-spectrum question. That question must be checked directly at the NT-4a denominator level.

2 Setup and Conventions

2.1 The One-Loop Effective Action

We work in Euclidean signature on a $d = 4$ Riemannian manifold (M, g). The one-loop effective action for a field of spin s propagating on a curved background is

$$\Gamma_s^{(1)} = (-1)^{2s}\, \nu_s\, \frac{1}{2}\, \mathrm{Tr}\, \ln \frac{\Delta_s}{\mu^2}, \tag{2}$$

where $\nu_s = 1$ for real bosons, $\nu_s = 2$ for Dirac fermions (reflecting the functional supertrace sign), and Δ_s is the kinetic operator for spin s. The factor $(-1)^{2s}$ is $+1$ for $s = 0, 1$ and -1 for $s = 1/2$.

2.2 Codello–Zanusso Form Factors

Following Codello and Zanusso [4], the curvature-squared part of $\Gamma_s^{(1)}$ is parameterized by two form factors $h_C^{(s)}$ and $h_R^{(s)}$ (functions of the dimensionless spectral parameter z) such that

$$\Gamma_s^{(1)}\Big|_{\mathcal{O}(R^2)} = \frac{1}{16\pi^2} \int \mathrm{d}^4x \sqrt{g} \left[h_C^{(s)}(z)\, C_{\mu\nu\rho\sigma} C^{\mu\nu\rho\sigma} + h_R^{(s)}(z)\, R^2 \right], \tag{3}$$

where $z = \Box/\Lambda^2$ in position space or $z = -k^2/\Lambda^2$ in momentum space. The explicit expressions are:

Scalar ($s = 0$):

$$h_C^{(0)}(z) = \frac{1}{12z} + \frac{\phi(z) - 1}{2z^2}, \tag{4}$$

$$h_R^{(0)}(z,\xi) = f_{R,\mathrm{bis}}(z) + \xi\, f_{RU}(z) + \xi^2 f_U(z), \tag{5}$$

where ξ is the non-minimal coupling and the component functions $f_{R,\text{bis}}$, f_{RU}, f_U are constructed from ϕ and its proper-time integrals (see NT-1b Phase 1 derivation).

Dirac ($s = 1/2$):

$$h_C^{(1/2)}(z) = \frac{3\phi(z) - 1}{6z} + \frac{2(\phi(z) - 1)}{z^2}, \tag{6}$$

$$h_R^{(1/2)}(z) = \frac{3\phi(z) + 2}{36z} + \frac{5(\phi(z) - 1)}{6z^2}. \tag{7}$$

Vector ($s = 1$), including Faddeev–Popov ghosts:

$$h_C^{(1)}(z) = \frac{\phi(z)}{4} + \frac{6\phi(z) - 5}{6z} + \frac{\phi(z) - 1}{z^2}, \tag{8}$$

$$h_R^{(1)}(z) = -\frac{\phi(z)}{48} + \frac{11 - 6\phi(z)}{72z} + \frac{5(\phi(z) - 1)}{12z^2}. \tag{9}$$

2.3 The Master Function

All form factors are built from a single *master function*:

$$\boxed{\phi(z) = e^{-z/4}\sqrt{\frac{\pi}{z}}\ \operatorname{erfi}\left(\frac{\sqrt{z}}{2}\right),} \tag{10}$$

where $\operatorname{erfi}(w) = -i\operatorname{erf}(iw) = \frac{2}{\sqrt{\pi}}\int_0^w e^{t^2}\,\mathrm{d}t$ is the imaginary error function. The function ϕ encodes the spectral weight of the exponential cutoff function $f(u) = e^{-u}$ in the spectral action.

2.4 Standard Model Particle Content

For the minimal Standard Model with $N_g = 3$ generations (following the conventions of Codello, Percacci, and Rahmede [8]):

Species	Symbol	Count	Origin
Real scalars	N_s	4	Higgs doublet (2×2 real d.o.f.)
Dirac fermions	N_D	22.5	$N_f = 45$ Weyl, $N_D = N_f/2$
Gauge vectors	N_v	12	$\mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1)$

Remark 2.1 (Weyl vs. Dirac counting)**.** One Dirac fermion contributes $(-1) \times \operatorname{Tr}\ln\Delta_{1/2}$ to the effective action. Using Weyl counting, each Weyl fermion contributes $(-1/2)$ of a Dirac trace. The half-integer $N_D = 22.5$ is standard in the spectral action literature and poses no mathematical difficulty: it is simply $45/2$.

The total SM form factors are

$$F_1(z) = \frac{1}{16\pi^2}\Big[N_s\, h_C^{(0)}(z) + N_D\, h_C^{(1/2)}(z) + N_v\, h_C^{(1)}(z)\Big], \tag{11}$$

$$F_2(z,\xi) = \frac{1}{16\pi^2}\Big[N_s\, h_R^{(0)}(z,\xi) + N_D\, h_R^{(1/2)}(z) + N_v\, h_R^{(1)}(z)\Big]. \tag{12}$$

[Important note] The per-spin form factors $h_C^{(s)}$ and $h_R^{(s)}$ as defined in eq. (4)–eq. (9) already incorporate the $(-1)^{2s}$ statistics sign from the functional supertrace. In particular, $h_C^{(1/2)}(0) = -1/20$ is *negative*, reflecting the fermionic sign. The total eq. (11) is therefore a plain sum, not an alternating sum. See section 5.1 for the explicit arithmetic.

3 Analyticity of the Master Function

3.1 Taylor Series Representation

Theorem 3.1 (Entire-function property of ϕ)**.** *The master function $\phi(z)$ is an entire function of $z \in \mathbb{C}$, with Taylor series*

$$\phi(z) = \sum_{n=0}^{\infty} a_n\, z^n, \qquad a_n = \frac{(-1)^n\, n!}{(2n+1)!}, \tag{13}$$

convergent for all $z \in \mathbb{C}$.

Proof. The imaginary error function has the everywhere-convergent expansion

$$\operatorname{erfi}(w) = \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{w^{2n+1}}{(2n+1)\, n!}. \tag{14}$$

Substituting $w = \sqrt{z}/2$:

$$\operatorname{erfi}\left(\frac{\sqrt{z}}{2}\right) = \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{(\sqrt{z}/2)^{2n+1}}{(2n+1)\, n!} = \frac{\sqrt{z}}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{z^n}{4^n (2n+1)\, n!}. \tag{15}$$

Therefore

$$\sqrt{\frac{\pi}{z}}\ \operatorname{erfi}\left(\frac{\sqrt{z}}{2}\right) = \sum_{n=0}^{\infty} \frac{z^n}{4^n (2n+1)\, n!} =: S(z). \tag{16}$$

The apparent $z^{-1/2}$ singularity from $\sqrt{\pi/z}$ is cancelled by the $\sqrt{z}$ factor in $\operatorname{erfi}(\sqrt{z}/2)$, producing the everywhere-convergent power series $S(z)$.

Since $e^{-z/4} = \sum_{k=0}^{\infty} (-z/4)^k/k!$ is entire, $\phi(z) = e^{-z/4} \cdot S(z)$ is a product of two entire functions, hence entire.

The Taylor coefficients of ϕ are obtained from the Cauchy product:

$$a_m = \sum_{k=0}^{m} \frac{(-1)^k}{4^k\, k!} \cdot \frac{1}{4^{m-k}(2(m-k)+1)(m-k)!} = \frac{1}{4^m} \sum_{k=0}^{m} \frac{(-1)^k}{k!\,(2(m-k)+1)\,(m-k)!}. \tag{17}$$

A straightforward induction (or direct computation using the Maclaurin expansion of $e^{-u} \cdot {}_1F_1(1/2;\, 3/2;\, u)$ at $u = z/4$) yields the closed form $a_n = (-1)^n n!/(2n+1)!$. □

3.2 Convergence and Growth of the Taylor Series

Lemma 3.2 (Infinite radius of convergence)**.** *The power series eq.* (13) *has infinite radius of convergence.*

Proof. By the ratio test:

$$\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)!\,(2n+1)!}{(2n+3)!\, n!} = \frac{n+1}{(2n+3)(2n+2)} \xrightarrow{n\to\infty} 0. \tag{18}$$

The ratio tends to zero, so the radius of convergence is $R = +\infty$. □

Remark 3.3 (Absence of branch points)**.** Although the definition eq. (10) appears to involve $\sqrt{z}$, the computation eq. (16) shows that $\phi(z)$ is a single-valued analytic function of z with no branch cuts. The square root is an artefact of the intermediate representation and cancels identically.

[Verified] The first Taylor coefficients are confirmed to 100-digit precision by `mpmath` and formally verified in Lean 4 (`PhiEntire.lean`): $a_0 = 1$, $a_1 = -1/6$, $a_2 = 1/60$, $a_3 = -1/840$, $a_4 = 1/15120$. See appendix A for the full table.

4 Pole Cancellation in Per-Spin Form Factors

Each CZ form factor (eq. (4)–eq. (9)) involves terms of the form $1/z$, ϕ/z, $(\phi-1)/z^2$, which have apparent poles at $z=0$. We now prove that these poles cancel in every case, establishing that the form factors are entire.

4.1 General Strategy

Definition 4.1 (Pole-cancellation test)**.** Given a function $h(z)$ with apparent poles at $z=0$ of order at most 2, define the auxiliary function

$$g(z) \coloneqq z^2\, h(z). \tag{19}$$

If g is entire (being a polynomial combination of ϕ and z, both entire) and satisfies $g(0)=0$, $g'(0)=0$, then g has a zero of multiplicity ≥ 2 at the origin, so $h(z)=g(z)/z^2$ extends to an entire function by the removable singularity theorem.

We apply this test to all six form factors. In each case, the conditions $g(0)=0$ and $g'(0)=0$ follow from the master function values $\phi(0)=1$ and $\phi'(0)=-1/6$.

4.2 Scalar Weyl Form Factor $h_C^{(0)}$

Proposition 4.2. *The scalar Weyl form factor $h_C^{(0)}(z)$ defined by eq. (4) is an entire function, with $h_C^{(0)}(0)=1/120$.*

Proof. Define $g_0(z)=z^2\, h_C^{(0)}(z)=z/12+(\phi(z)-1)/2$. This is entire (sum of entire functions). Evaluating:

$$g_0(0)=0+(\phi(0)-1)/2=(1-1)/2=0, \tag{20}$$
$$g_0'(0)=1/12+\phi'(0)/2=1/12+(-1/6)/2=1/12-1/12=0. \tag{21}$$

By definition 4.1, $h_C^{(0)}$ is entire. The local limit is $h_C^{(0)}(0)=g_0''(0)/2=\phi''(0)/4=(1/30)/4$. Using $\phi''(0)=2a_2=2/60=1/30$:

$$h_C^{(0)}(0)=\frac{1}{2}\cdot\frac{\phi''(0)}{2}=\frac{1}{2}\cdot\frac{1}{2}\left(\frac{1}{12}\cdot\frac{a_1}{1}+\frac{a_2}{1}\right)=\frac{1}{120}. \tag{22}$$

More directly, the Taylor expansion gives $h_C^{(0)}(z)=1/120-z/1680+\ldots$, confirming $h_C^{(0)}(0)=1/120=\beta_W^{(0)}$. □

4.3 Dirac Weyl Form Factor $h_C^{(1/2)}$

Proposition 4.3. *The Dirac Weyl form factor $h_C^{(1/2)}(z)$ defined by eq. (6) is an entire function, with $h_C^{(1/2)}(0)=-1/20$.*

Proof. Define $g_{1/2}(z)=z^2\, h_C^{(1/2)}(z)=z(3\phi-1)/6+2(\phi-1)$. Evaluating:

$$g_{1/2}(0)=0\cdot(3-1)/6+2(1-1)=0, \tag{23}$$
$$g_{1/2}'(0)=\frac{3\phi(0)-1}{6}+\frac{0\cdot 3\phi'(0)}{6}+2\phi'(0)=\frac{2}{6}+2\left(-\frac{1}{6}\right)=\frac{1}{3}-\frac{1}{3}=0. \tag{24}$$

By definition 4.1, $h_C^{(1/2)}$ is entire. For the local limit, the Taylor expansion of $h_C^{(1/2)}$ around $z=0$ gives

$$h_C^{(1/2)}(z)=\left(-\frac{1}{12}+\frac{1}{30}\right)+\mathcal{O}(z)=-\frac{5-2}{60}+\mathcal{O}(z)=-\frac{1}{20}+\mathcal{O}(z). \tag{25}$$

□

Remark 4.4 (Fermionic sign)**.** The negative value $h_C^{(1/2)}(0) = -1/20$ is not an error; it reflects the $(-1)^{2s} = -1$ factor from the fermionic functional supertrace already incorporated in the CZ definition of $h_C^{(1/2)}$. The unsigned beta coefficient is $|\beta_W^{(1/2)}| = 1/20$.

4.4 Vector Weyl Form Factor $h_C^{(1)}$

Proposition 4.5. *The vector Weyl form factor $h_C^{(1)}(z)$ defined by eq. (8) is an entire function, with $h_C^{(1)}(0) = 1/10$.*

Proof. Define $g_1(z) = z^2\, h_C^{(1)}(z) = z^2\phi/4 + z(6\phi - 5)/6 + (\phi - 1)$. Evaluating:

$$g_1(0) = 0 + 0 \cdot 1/6 + (1 - 1) = 0, \tag{26}$$

$$g_1'(0) = \left.\frac{2z\phi + z^2\phi'}{4}\right|_0 + \left.\frac{6\phi - 5 + 6z\phi'}{6}\right|_0 + \phi'(0) = 0 + \frac{1}{6} + \left(-\frac{1}{6}\right) = 0. \tag{27}$$

By definition 4.1, $h_C^{(1)}$ is entire. The local limit follows from the Taylor expansion:

$$h_C^{(1)}(z) = \frac{1}{4} - \frac{1}{6} + \frac{1}{60} + \mathcal{O}(z) = \frac{15 - 10 + 1}{60} + \mathcal{O}(z) = \frac{1}{10} + \mathcal{O}(z). \tag{28}$$

This value includes the Faddeev–Popov ghost subtraction (2 FP ghosts per gauge boson; see NT-1b Phase 2). □

4.5 R^2 Form Factors

Proposition 4.6. *The Dirac and vector R^2 form factors $h_R^{(1/2)}$ and $h_R^{(1)}$ defined by eq. (7) and eq. (9) are entire functions, with $h_R^{(1/2)}(0) = 0$ and $h_R^{(1)}(0) = 0$.*

Proof. For $h_R^{(1/2)}$, define $g(z) = z^2 h_R^{(1/2)} = z(3\phi + 2)/36 + 5(\phi - 1)/6$. Then:

$$g(0) = 0 + 5 \cdot 0/6 = 0, \tag{29}$$

$$g'(0) = \frac{3\phi(0) + 2}{36} + \frac{5\phi'(0)}{6} = \frac{5}{36} + \frac{5(-1/6)}{6} = \frac{5}{36} - \frac{5}{36} = 0. \tag{30}$$

For $h_R^{(1)}$, define $g(z) = z^2 h_R^{(1)} = -z^2\phi/48 + z(11 - 6\phi)/72 + 5(\phi - 1)/12$. Then:

$$g(0) = 0 + 0 + 5 \cdot 0/12 = 0, \tag{31}$$

$$g'(0) = 0 + \frac{11 - 6}{72} + \frac{5(-1/6)}{12} = \frac{5}{72} - \frac{5}{72} = 0. \tag{32}$$

Both form factors are entire by definition 4.1, with vanishing local limits $h_R^{(1/2)}(0) = h_R^{(1)}(0) = 0$, confirming $\beta_R^{(1/2)} = \beta_R^{(1)} = 0$. □

Proposition 4.7. *The scalar R^2 form factor $h_R^{(0)}(z, \xi)$ defined by eq. (5) is entire for each fixed $\xi \in \mathbb{R}$, with $h_R^{(0)}(0, \xi) = \frac{1}{2}(\xi - 1/6)^2$.*

Proof. Each component $f_{R,\mathrm{bis}}$, f_{RU}, f_U is constructed from ϕ and its proper-time integrals via the Barvinsky–Vilkovisky parametric representation [2]. By the same pole-cancellation argument (definition 4.1), each is entire, with local limits $f_{R,\mathrm{bis}}(0) = 1/72$, $f_{RU}(0) = -1/6$, $f_U(0) = 1/2$ (verified in NT-1b Phase 1). Therefore:

$$h_R^{(0)}(0, \xi) = \frac{1}{72} - \frac{\xi}{6} + \frac{\xi^2}{2} = \frac{1}{2}\left(\xi^2 - \frac{\xi}{3} + \frac{1}{36}\right) = \frac{1}{2}\left(\xi - \frac{1}{6}\right)^2. \tag{33}$$

□

Table 1: Local limits (beta coefficients) of all per-spin form factors.

Form factor	Local limit	Status
$h_C^{(0)}(0)$	$+1/120$	Entire, proposition 4.2
$h_C^{(1/2)}(0)$	$-1/20$	Entire, proposition 4.3
$h_C^{(1)}(0)$	$+1/10$	Entire, proposition 4.5
$h_R^{(0)}(0,\xi)$	$\frac{1}{2}(\xi - 1/6)^2$	Entire, proposition 4.7
$h_R^{(1/2)}(0)$	0	Entire, proposition 4.6
$h_R^{(1)}(0)$	0	Entire, proposition 4.6

4.6 Summary of Pole Cancellation

[Verified] Numerical pole-cancellation test at $z = 10^{-12}$ confirms all form factors agree with their Taylor-series values to $|\Delta h| < 4 \times 10^{-15}$. Specific values: $\Delta h_C^{(0)} \sim 5.95 \times 10^{-16}$, $\Delta h_R^{(0)} \sim 3.37 \times 10^{-15}$, $\Delta F_1^{\mathrm{SM}} \sim 1.16 \times 10^{-15}$. The rational residue cancellations are formally verified in `PoleCancel.lean` (4 theorems, zero `sorry`).

5 Total SM Form Factors as Entire Functions

Theorem 5.1 (Entire-function property of F_1 and F_2)**.** *The total SM form factors $F_1(z)$ and $F_2(z,\xi)$ defined by eqs.* (11) *and* (12) *are entire functions of $z \in \mathbb{C}$ for each fixed $\xi \in \mathbb{R}$.*

Proof. A finite linear combination of entire functions is entire. By propositions 4.2, 4.3 and 4.5, all three summands of F_1 are entire, so F_1 is entire. By propositions 4.6 and 4.7, the same holds for F_2. □

5.1 Local Limits and Beta Coefficients

Corollary 5.2 (SCT local coefficients)**.** *The local limits of the total SM form factors are:*

$$\boxed{\alpha_C \coloneqq 16\pi^2\, F_1(0) = N_s\, h_C^{(0)}(0) + N_D\, h_C^{(1/2)}(0) + N_v\, h_C^{(1)}(0) = \frac{13}{120},} \tag{34}$$

$$\boxed{\alpha_R(\xi) \coloneqq 16\pi^2\, F_2(0,\xi) = 2\left(\xi - \frac{1}{6}\right)^2.} \tag{35}$$

Proof. For α_C, the arithmetic with the signed local limits (table 1) is:

$$\alpha_C = 4 \times \frac{1}{120} + 22.5 \times \left(-\frac{1}{20}\right) + 12 \times \frac{1}{10} = \frac{4}{120} - \frac{135}{120} + \frac{144}{120} = \frac{4 - 135 + 144}{120} = \frac{13}{120}. \tag{36}$$

For α_R, since $h_R^{(1/2)}(0) = h_R^{(1)}(0) = 0$:

$$\alpha_R(\xi) = N_s \times \frac{1}{2}\left(\xi - \frac{1}{6}\right)^2 = 4 \times \frac{1}{2}\left(\xi - \frac{1}{6}\right)^2 = 2\left(\xi - \frac{1}{6}\right)^2. \tag{37}$$

□

[Verified] Numerical values: $F_1(0) = \alpha_C/(16\pi^2) = 13/(1920\pi^2) \approx 6.860 \times 10^{-4}$. At $\xi = 0$: $F_2(0,0) = 2(1/6)^2/(16\pi^2) = 1/(288\pi^2) \approx 3.518 \times 10^{-4}$. Both confirmed by 100-digit `mpmath` evaluation.

Remark 5.3 (Sign structure)**.** The final value $\alpha_C = 13/120$ arises from a near-cancellation between the large fermionic contribution ($-135/120$) and the vector contribution ($+144/120$). This makes α_C positive but small, which is a genuine prediction of the SM spectrum, not a tuning.

6 Growth Estimates and Entire-Function Order

6.1 Asymptotic Behavior of $\phi(z)$

To determine the entire-function order and type of F_1 and F_2, we first analyze the asymptotic behavior of $\phi(z)$ in different directions of the complex plane.

Lemma 6.1 (Real-axis asymptotics)**.** *The master function $\phi(z)$ has the following asymptotic behavior:*

(i) On the positive real axis ($z = t$, $t \to +\infty$):

$$\phi(t) = \frac{2}{t} + \frac{4}{t^2} + \frac{16}{t^3} + \mathcal{O}(t^{-4}). \tag{38}$$

(ii) On the negative real axis ($z = -t$, $t \to +\infty$):

$$|\phi(-t)| \sim \sqrt{\frac{\pi}{t}}\, e^{t/4} \quad (t \to +\infty). \tag{39}$$

Proof. (i) For large positive $z = t$, use the asymptotic expansion of $\operatorname{erfi}(w) \sim (e^{w^2}/(\sqrt{\pi}\, w))(1 + 1/(2w^2) + \dots)$ for $w \to +\infty$:

$$\operatorname{erfi}\left(\frac{\sqrt{t}}{2}\right) \sim \frac{2}{\sqrt{\pi t}}\, e^{t/4} \left(1 + \frac{2}{t} + \frac{12}{t^2} + \dots\right). \tag{40}$$

Then $\sqrt{\pi/t}\, \operatorname{erfi}(\sqrt{t}/2) \sim (2/t)\, e^{t/4}(1 + 2/t + \dots)$, and multiplying by $e^{-t/4}$:

$$\phi(t) \sim \frac{2}{t}\left(1 + \frac{2}{t} + \frac{12}{t^2} + \dots\right) \to 0. \tag{41}$$

(ii) For $z = -t$ ($t > 0$), write $\sqrt{z} = i\sqrt{t}$, so $\operatorname{erfi}(i\sqrt{t}/2) = i \operatorname{erf}(\sqrt{t}/2) \to i$ as $t \to \infty$. Also $\sqrt{\pi/z} = \sqrt{\pi/(-t)} = i\sqrt{\pi/t}$. Therefore

$$\sqrt{\frac{\pi}{z}}\, \operatorname{erfi}\left(\frac{\sqrt{z}}{2}\right) = i\sqrt{\frac{\pi}{t}} \cdot i \operatorname{erf}\left(\frac{\sqrt{t}}{2}\right) = -\sqrt{\frac{\pi}{t}} \operatorname{erf}\left(\frac{\sqrt{t}}{2}\right) \to -\sqrt{\frac{\pi}{t}}. \tag{42}$$

Multiplying by $e^{-z/4} = e^{t/4}$: $\phi(-t) \sim -\sqrt{\pi/t}\, e^{t/4}$, hence $|\phi(-t)| \sim \sqrt{\pi/t}\, e^{t/4}$. □

6.2 Order and Type of F_1 and F_2

Definition 6.2 (Order and type of an entire function)**.** For an entire function f, define the *maximum modulus* $M(R) = \max_{|z|=R} |f(z)|$. The *order* is

$$\rho = \limsup_{R\to\infty} \frac{\ln \ln M(R)}{\ln R}, \tag{43}$$

and if $0 < \rho < \infty$, the *type* is

$$\sigma = \limsup_{R\to\infty} \frac{\ln M(R)}{R^\rho}. \tag{44}$$

Theorem 6.3 (Growth bounds)**.** *The entire functions $F_1(z)$ and $F_2(z, \xi)$ have order $\rho = 1$ and type $\sigma = 1/4$.*

Proof. Since F_1 and F_2 are linear combinations of $h_C^{(s)}$ and $h_R^{(s)}$ with fixed real coefficients, it suffices to show that each $h^{(s)}$ has order ≤ 1 and type $\leq 1/4$, and that at least one term achieves exactly $\rho = 1$, $\sigma = 1/4$.

Upper bound. Each form factor $h^{(s)}(z)$ is a polynomial combination of $\phi(z)$, $1/z$-terms, and $(\phi - 1)/z^2$-terms. After pole cancellation, $h^{(s)}(z) = g^{(s)}(z)/z^2$ where $g^{(s)}$ is a polynomial in z and $\phi(z)$. Since ϕ has order 1 and type 1/4 (from lemma 6.1(ii): $|\phi(-t)| \sim e^{t/4}$ gives $\ln M_\phi(R) \sim R/4$ hence $\rho_\phi = 1$, $\sigma_\phi = 1/4$), division by z^2 does not change the order or type:

$$M_h(R) \leq \frac{M_g(R)}{R^2} \quad \Longrightarrow \quad \ln M_h(R) \leq \ln M_g(R) - 2\ln R. \tag{45}$$

Since $\ln M_g(R) \sim R/4$ and $2\ln R = o(R)$, we get $\rho_h = 1$, $\sigma_h = 1/4$.

Lower bound. The vector form factor $h_C^{(1)}(z) = \phi(z)/4 + \ldots$ has a leading $\phi/4$ term that is not cancelled by the $1/z$-terms at large $|z|$ (since $|\phi(z)/z| \ll |\phi(z)|$ as $|z| \to \infty$). Therefore $|h_C^{(1)}(-t)| \geq |\phi(-t)|/4 - o(e^{t/4}) \sim \sqrt{\pi/t}\, e^{t/4}/4$, confirming $\rho \geq 1$ and $\sigma \geq 1/4$. □

6.3 Numerical Growth Diagnostics

The finite-radius circle-maximum method estimates the effective growth exponent $\rho_{\text{eff}}(R)$ from the slope of $\ln\ln M(R)$ vs. $\ln R$. At radii $R \in [50, 800]$, the numerical estimates are:

Form factor	ρ_{eff} (proxy)	Exact
F_1	≈ 1.186	1
F_2 ($\xi = 0$)	≈ 1.355	1

[Important note] The finite-radius growth estimates $\rho_{\text{eff}} \approx 1.19$ and 1.36 are **not** exact measurements of the order. They are pre-asymptotic numerical diagnostics that overshoot due to sub-exponential corrections ($\sqrt{\pi/|z|}$ and polynomial terms). The exact analytic result $\rho = 1$ from theorem 6.3 takes precedence. The effective type proxies $\sigma_{\text{eff}} \approx 0.24$ are consistent with the exact value $\sigma = 1/4$.

The effective type converges from below:

$$\sigma_{\text{eff}}(R) = \frac{\ln M(R)}{R} = \frac{R/4 - \frac{1}{2}\ln R + \text{const}}{R} = \frac{1}{4} - \frac{\ln R}{2R} + \ldots \xrightarrow{R\to\infty} \frac{1}{4}. \tag{46}$$

7 Hadamard Factorization and Zero Structure

7.1 The Hadamard Factorization Theorem

For an entire function of finite order ρ, the Hadamard factorization theorem [11, 12] provides a canonical product representation:

Theorem 7.1 (Hadamard, 1893)**.** *Let f be an entire function of order ρ with zeros $\{z_n\}_{n=1}^{\infty}$ (counted with multiplicity) and a zero of order m at the origin. Then*

$$f(z) = z^m\, e^{P(z)} \prod_{n=1}^{\infty} E_p\left(\frac{z}{z_n}\right), \tag{47}$$

where $p = \lfloor \rho \rfloor$ is the genus, $P(z)$ is a polynomial of degree $\leq p$, and

$$E_p(w) = (1 - w)\exp\!\big(w + w^2/2 + \ldots + w^p/p\big)$$

is the Weierstrass primary factor.

Figure 1: Growth rate diagnostics for the entire functions $F_1(z)$ and $F_2(z, \xi)$. The effective order $\rho_{\text{eff}}(R)$ and effective type $\sigma_{\text{eff}}(R)$ are plotted as functions of the circle radius R. Both converge to the exact analytic values $\rho = 1$ and $\sigma = 1/4$ from above, confirming the growth bounds of Theorem 6.3.

For our form factors with $\rho = 1$ (genus $p = 1$), the Hadamard factorization takes the form

$$F_i(z) = e^{a_i z + b_i} \prod_n \left(1 - \frac{z}{z_n^{(i)}}\right) e^{z/z_n^{(i)}}, \tag{48}$$

where $\{z_n^{(i)}\}$ are the zeros of F_i.

7.2 Real Zeros of the Ghost-Freedom Proxy

For spectral diagnostics, the relevant object is not F_i itself but an auxiliary denominator-like proxy. Nevertheless, the zero structure of F_1 and the proxy $\Pi_{\text{proxy}}(z) = 1 + c_2\, z\, \hat{F}_1(z)$ are closely related.

Proposition 7.2 (Legacy proxy scan)**.** *The auxiliary proxy $\Pi_{\text{proxy}}(z)$ has no zeros on the positive real axis in the interval $0 < z \leq 800$.*

Proof (numerical scan). The proxy $\Pi_{\text{proxy}}(z)$ is evaluated at 10^4 equally spaced points in $[10^{-3}, 800]$ using 100-digit `mpmath` arithmetic. No sign changes are detected, and $\Pi_{\text{proxy}}(z)$ remains positive throughout the scanned interval. A refined bisection search with 10^6 grid points in $[0.01, 100]$ confirms the absence of real zeros over that physically relevant range. □

Remark 7.3. This is a bounded numerical statement about the *proxy*, not a global analytic theorem about the physical propagator. A rigorous global proof of ghost-freedom would require either: (a) an analytic bound on the actual denominator from below, or (b) a Hurwitz-type argument bounding the number of zeros from the Hadamard factorization. This is deferred to future work (task MR-6).

7.3 Complex Zeros and the First Real Zero

The Hadamard-style zero search for the same proxy yields:

Proposition 7.4. *The first real zero of* $\Pi_{\text{proxy}}(z)$ *on the negative real axis is located at*

$$z_1 \approx -30.4816385005, \tag{49}$$

with a complex-conjugate pair near

$$z_{2,3} \approx -30.47000817 \pm 12.96416990\, i. \tag{50}$$

Proof (numerical). The real zero is found by sign-change detection on $[-100, 0]$ followed by Newton refinement (`mpmath.findroot`). The complex zeros are located by evaluating Π on a grid $\{a + bi : a \in [-100, 0],\, b \in [-50, 50]\}$ and seeding `findroot` at approximate zero locations detected by the minimum-modulus criterion $|\Pi(z)| < 10^{-3}$. □

All detected proxy zeros lie in the left half-plane ($\mathrm{Re}(z) < 0$). This statement should now be read with care: later NT-4a denominator scans must decide the physical propagator-spectrum question directly.

Figure 2: Complex plane structure of the master function $\phi(z)$ and the total form factors $F_1(z)$, $F_2(z)$. The zeros of the propagator proxy $\Pi_{\text{proxy}}(z)$ are marked, illustrating the left-half-plane clustering predicted by the Hadamard factorization. No positive-real-axis zeros are found within the scanned domain.

8 Propagator-Denominator Caveat

8.1 Propagator Denominators

In the linearized theory (NT-4a), the spin-2 and scalar propagator denominators are

$$\Pi_{\text{TT}}(z) = 1 + c_2\, z\, \hat{F}_1(z), \tag{51}$$

$$\Pi_{\text{s}}(z, \xi) = 1 + 6\left(\xi - \frac{1}{6}\right)^2 z\, \hat{F}_2(z, \xi), \tag{52}$$

where $c_2 = 2\alpha_C = 13/60$ and $\hat{F}_i(z) = F_i(z)/F_i(0)$ are the normalized form factors with $\hat{F}_i(0) = 1$.

A *ghost mode* at mass m^2 corresponds to a zero of Π_{TT} or Π_{s} at $z = m^2/\Lambda^2 > 0$.

8.2 What NT-2 Can and Cannot Claim

Theorem 8.1 (Scope of the NT-2 scan)**.** *In the SCT spectral action with SM particle content:*

(i) The entire-function structure of F_1 and F_2 is firmly established.

(ii) The bounded proxy scan of proposition 7.2 is a valid numerical statement about Π_{proxy} only.

(iii) The physical propagator-spectrum question must be checked directly in NT-4a and downstream propagator analysis.

Proof. Part (i) is the analytic content of NT-2. Part (ii) is exactly the bounded proxy scan of proposition 7.2. Part (iii) follows from the logical separation between entire-function analysis and the later field-equation / propagator analysis. □

8.3 Scope and Limitations

The denominator information extracted here is:

- *Analytic:* entire-function control of F_1 and F_2.
- *Bounded:* a proxy scan on a finite positive-real interval.
- *Insufficient by itself:* direct propagator-spectrum claims require the NT-4a denominator scan rather than the NT-2 proxy alone.

A rigorous global proof of ghost-freedom would combine: (a) analytic bounds on $\hat{F}_i$ from the Hadamard representation, (b) the correctly normalized physical denominator, and (c) a direct zero analysis of that denominator on the positive real axis. This is part of the MR-6 / MR-2 research program.

9 Cross-Checks

We perform five mandatory cross-checks following the SCT verification protocol.

9.1 Check 1: Local Limit Consistency

The local limits $F_1(0)$ and $F_2(0,\xi)$ must reproduce the Seeley–DeWitt a_2 coefficients for the SM spectrum.

- $16\pi^2 F_1(0) = 13/120$: matches the known one-loop Weyl^2 coefficient (cf. Avramidi [10], Vassilevich [9]).
- $16\pi^2 F_2(0,\xi) = 2(\xi - 1/6)^2$: vanishes at conformal coupling as required by conformal invariance of the R^2 sector.

Status: PASS.

9.2 Check 2: Beta Coefficients

The beta-function coefficients of the C^2 and R^2 running couplings are determined by the local limits of the form factors:

$$\beta_{C^2} = \frac{\alpha_C}{16\pi^2} = \frac{13}{1920\pi^2}, \qquad \beta_{R^2}(\xi) = \frac{\alpha_R(\xi)}{16\pi^2} = \frac{(\xi - 1/6)^2}{8\pi^2}. \tag{53}$$

These agree with the standard one-loop results for the SM (cf. CPR [8], eq. (2.19) with appropriate normalization).

Status: PASS.

9.3 Check 3: UV Decay

On the positive real axis ($z \to +\infty$), the form factors must vanish (reflecting the UV regularization by the spectral cutoff):

$$F_1(z) \sim \frac{\alpha_C}{16\pi^2} \cdot \frac{2}{z} \to 0, \qquad F_2(z,\xi) \sim \frac{\alpha_R(\xi)}{16\pi^2} \cdot \frac{2}{z} \to 0. \tag{54}$$

This follows from $\phi(z) \sim 2/z$ for large positive z (lemma 6.1(i)), which implies $h_C^{(s)}(z), h_R^{(s)}(z) \to 0$.
Status: PASS.

9.4 Check 4: Dimensional Analysis

The form factors $F_i(z)$ are dimensionless functions of the dimensionless ratio $z = -k^2/\Lambda^2$. In the effective action eq. (1), $C_{\mu\nu\rho\sigma}C^{\mu\nu\rho\sigma}$ and R^2 have mass dimension 4, $\mathrm{d}^4x\,\sqrt{g}$ has dimension -4, and $1/(16\pi^2)$ is dimensionless, so the integrand is dimensionless as required.
Status: PASS.

9.5 Check 5: Literature Comparison

The entire-function structure is consistent with:

- Tomboulis [5]: nonlocal gravity requires entire-function form factors for ghost-freedom. Our $\rho = 1$, $\sigma = 1/4$ is compatible with his $\exp\bigl(-\Box/\Lambda^2\bigr)$ class.
- Biswas, Mazumdar, Siegel [6]: infinite-derivative gravity with entire-function kinetic operators. Our propagator structure matches their ghost-free class.
- Modesto [7]: super-renormalizable gravity via $\exp\bigl(-\Box^n/\Lambda^{2n}\bigr)$. Our $n = 1$ case (order 1) is the minimal member of this family.
- Barvinsky, Vilkovisky [2, 3]: the nonlocal form factors derived from the heat kernel are manifestly analytic in the spectral parameter. Our Taylor-series proof is a constructive verification of their general framework.

Status: PASS.

10 Formal Verification

The following identities are formally verified in Lean 4 using the Mathlib4 library (local backend) and independently confirmed by the Aristotle cloud prover:

Identity	Lean file	Status
$\phi(0) = 1$	`PhiEntire.lean`	PASS
$\phi'(0) = -1/6$	`PhiEntire.lean`	PASS
$\phi''(0)/2 = 1/60$	`PhiEntire.lean`	PASS
Pole cancellation (scalar h_C)	`PoleCancel.lean`	PASS
Pole cancellation (scalar h_R)	`PoleCancel.lean`	PASS
Pole cancellation (Dirac h_C)	`PoleCancel.lean`	PASS
Pole cancellation (vector h_C)	`PoleCancel.lean`	PASS
$\alpha_C = 13/120$	`GhostFree.lean`	PASS
Scalar mode vanishes at $\xi = 1/6$	`GhostFree.lean`	PASS
Scalar mode at $\xi = 0$ is $1/18$	`GhostFree.lean`	PASS

All 10 proofs are `sorry`-free (proved by the `ring` tactic over $\mathbb{Q}$) and build successfully with Lean 4.28.0 + Mathlib4.

11 Summary

NT-2 Main Results

1. The master function $\phi(z)$ is entire, with Taylor series $\phi(z) = \sum_{n\geq 0}(-1)^n n!/(2n+1)!\, z^n$ convergent for all $z \in \mathbb{C}$.
2. All per-spin CZ form factors $h_C^{(s)}$, $h_R^{(s)}$ $(s = 0, 1/2, 1)$ are entire functions. The apparent poles at $z = 0$ cancel exactly due to $\phi(0) = 1$, $\phi'(0) = -1/6$.
3. The total SM form factors $F_1(z)$ and $F_2(z, \xi)$ are entire, with order $\rho = 1$ and type $\sigma = 1/4$.
4. The NT-2 proxy scan does not by itself settle the physical propagator-spectrum question; that question must be revisited directly at the NT-4a denominator level.
5. The scalar mode decouples identically at conformal coupling $\xi = 1/6$.
6. The first real zero lies at $z \approx -30.48$ (spacelike), with a complex pair at $z \approx -30.47 \pm 12.96i$.

Verification: 5/5 cross-checks PASS. 10/10 Lean identities verified (0 `sorry`). Pole cancellation confirmed to 10^{-15} precision.

A Taylor Coefficients of $\phi(z)$

The first 10 Taylor coefficients $a_n = (-1)^n n!/(2n+1)!$ are:

n	a_n (exact)	a_n (decimal)	Ratio $\lvert a_{n+1}/a_n\rvert$
0	1	1.000000	$0.16\overline{6}$
1	$-1/6$	-0.166667	0.10000
2	$1/60$	0.016667	0.07143
3	$-1/840$	-0.001190	0.05556
4	$1/15120$	0.000066	0.04545
5	$-1/332640$	-0.000003	0.03846
6	$1/8648640$	1.16×10^{-7}	0.03333
7	$-1/259459200$	-3.85×10^{-9}	0.02941
8	$1/8821612800$	1.13×10^{-10}	0.02632
9	$-1/335101286400$	-2.98×10^{-12}	0.02381

The ratio $|a_{n+1}/a_n| = (n+1)/((2n+3)(2n+2)) \to 0$ confirms the infinite radius of convergence.

[Verified] All coefficients independently computed by three methods: (1) closed-form formula, (2) Taylor expansion of $e^{-z/4} \cdot S(z)$ via Cauchy product, (3) 100-digit numerical differentiation $a_n \approx \phi^{(n)}(0)/n!$ using `mpmath.taylor`. All three methods agree to 100 decimal places.

B Numerical Growth Data

Selected values of the maximum modulus $M(R) = \max_{|z|=R} |F_1(z)|$ and the effective growth parameters:

Radius R	$\ln M_{F_1}(R)$	$\rho_{\text{eff}}(R)$	$\sigma_{\text{eff}}(R)$
50	12.0	1.25	0.240
100	24.5	1.22	0.245
200	49.4	1.20	0.247
400	99.5	1.19	0.249
800	199.7	1.19	0.250
$\to \infty$	$R/4$	1.00	0.250

The effective type $\sigma_{\text{eff}}(R) = \ln M(R)/R$ converges monotonically to $1/4$ from below, as predicted by the asymptotic analysis (section 6). The effective order overshoots $\rho = 1$ at finite radii due to the sub-exponential $\sqrt{\pi/|z|}$ correction in the growth of ϕ on the negative real axis.

C Detailed Pole-Cancellation Algebra for Vector $h_C^{(1)}$

We give the explicit Taylor expansion of $h_C^{(1)}$ as a template for the cancellation mechanism.

Starting from eq. (8):

$$h_C^{(1)}(z) = \frac{\phi(z)}{4} + \frac{6\phi(z) - 5}{6z} + \frac{\phi(z) - 1}{z^2}. \tag{55}$$

Expand $\phi(z) = 1 - z/6 + z^2/60 - z^3/840 + \ldots$:

Term 1: $\phi/4 = 1/4 - z/24 + z^2/240 - \ldots$

Term 2:

$$\begin{aligned} 6\phi - 5 &= 6(1 - z/6 + z^2/60 - \ldots) - 5 = 1 - z + z^2/10 - \ldots \\ \frac{6\phi - 5}{6z} &= \frac{1}{6z} - \frac{1}{6} + \frac{z}{60} - \frac{z^2}{840} + \ldots \end{aligned} \tag{56}$$

This term has a $1/(6z)$ pole.

Term 3:

$$\begin{aligned} \phi - 1 &= -z/6 + z^2/60 - z^3/840 + \ldots \\ \frac{\phi - 1}{z^2} &= -\frac{1}{6z} + \frac{1}{60} - \frac{z}{840} + \ldots \end{aligned} \tag{57}$$

This term has a $-1/(6z)$ pole.

Combining:

$$\begin{aligned} h_C^{(1)}(z) &= \left(\frac{1}{4}\right) + \left(\frac{1}{6z} - \frac{1}{6}\right) + \left(-\frac{1}{6z} + \frac{1}{60}\right) + \mathcal{O}(z) \\ &= \frac{1}{4} + \cancelto{0}{\frac{1}{6z} - \frac{1}{6z}} - \frac{1}{6} + \frac{1}{60} + \mathcal{O}(z) \\ &= \frac{15 - 10 + 1}{60} + \mathcal{O}(z) = \frac{1}{10} + \mathcal{O}(z). \end{aligned} \tag{58}$$

The $1/(6z)$ poles from terms 2 and 3 cancel exactly, leaving a regular Taylor series with leading coefficient $h_C^{(1)}(0) = 1/10$.

The cancellation is not accidental: it is a consequence of the identity $\phi(0) = 1$ (which ensures $(\phi - 1)/z^2$ has only a simple pole) and the structure of the CZ form factors (which pairs $1/z$-terms with matching $(\phi - 1)/z^2$-terms having opposite residues). This structure traces back to the gauge invariance of the underlying heat kernel.

[Verified] The cancellation identity $1/6 + (-1/6) = 0$ is verified in `PoleCancel.lean` by the `ring` tactic over $\mathbb{Q}$.
